As an example, this split is based on the condition “income == 10.” For this case, left Gini impurity is 0.44, right Gini impurity is 0.32, and weigthed Gini impurity is 0.37.

As an example, this split is based on the condition “stratum == 4.” For this case, left Gini impurity is 0.44, right Gini impurity is 0.5, and weigthed Gini impurity is 0.45.

Planning system for deliveries in Medellín

Catalina Patiño-Forero, Mateo Agudelo-Toro, Mauricio Toro

Here we present the implementation of an application capable of planning the shortest delivery route in the city of Medellín, Colombia. We discuss the different approaches to this problem which is similar to the famous Traveling Salesman Problem (TSP), but differs in the fact that, in our problem, we can visit each place (or vertex) more than once. Solving this problem is important since it would help people, especially stores with delivering services, to save time and money spent in fuel, because they can plan any route in an efficient way.
